

decision rule

2020-03-19

For the model:

$$Y_{ji} = S_{ji}(\beta_j + b_{ji} + \Gamma_j(\alpha'x_{ji})) + \epsilon_{ji}, \quad j \in \{1, 2\}$$

Parameter settings

I have tried different parameter settings.

Setting 1:

The fixed effect β :

	intercept	slope	concavity
Drug	18.6	-2.3	0.17
Placebo	18.6	-1.9	0.14

The fixed effect Γ :

	intercept	slope	concavity
Drug	0	1	0
Placebo	0	$\cos(\theta)$	$\sin(\theta)$

The random effect's covariance matrix:

	Drug				Placebo		
	intercept	slope	concavity		intercept	slope	concavity
intercept	8.869	2.766	-0.359	intercept	9.507	1.012	-0.093
slope	2.766	1.016	-0.104	slope	1.012	3.856	-0.395
concavity	-0.359	-0.104	1.5	concavity	-0.093	-0.395	1.5

Setting 2:

EMBARC's parameter

The random effect's covariance matrix:

	Drug				Placebo		
	intercept	slope	concavity		intercept	slope	concavity
intercept	8.869	2.766	-0.359	intercept	9.507	1.012	-0.093
slope	2.766	1.016	-0.104	slope	1.012	3.856	-0.395
concavity	-0.359	-0.104	0.015	concavity	-0.093	-0.395	0.045

Setting 3:

Make the intercept smaller

The fixed effect β :

	intercept	slope	concavity
Drug	1	-2.3	1.5
Placebo	1.1	-1.9	1

The fixed effect Γ :

	intercept	slope	concavity
Drug	0	1	0
Placebo	0	$\cos(\theta)$	$\sin(\theta)$

The random effect's covariance matrix:

	Drug				Placebo		
	intercept	slope	concavity		intercept	slope	concavity
intercept	4	0	0	intercept	4	1.732	1
slope	0	9	0	slope	1.732	1.75	0.433
concavity	0	0	1	concavity	1	0.433	1.25

Concordance proportion calculation

For the training dataset, we simulate $n = 100$ in each treatment group (200 subjects in total). The covariates are generated from $X \sim MVN(0, \Sigma)$, where

$$\Sigma_x = \begin{pmatrix} 1 & \rho & \dots & \rho \\ \rho & 1 & \dots & \rho \\ \dots & \dots & \dots & \dots \\ \rho & \dots & \rho & 1 \end{pmatrix}_{p \times p}$$

The outcome Y is then generated from the model

$$Y_{ji} = S_{ji}(\beta_j + b_{ji} + \Gamma_j(\alpha' x_{ji})) + \epsilon_{ji}, \quad j \in \{1, 2\}$$

For the testing dataset, $N = 1000$ subjects are generated. For each subjects, the outcome if he or she get treatment and the outcome if he or she get placebo are both generated.

For the testing dataset, since we have both outcomes, we know the treatment group assignment for each subject.

$$\text{group assignment} = \begin{cases} \text{Drug group} & \Delta Y_{pbo} > \Delta Y_{drg} \\ \text{Placebo group} & \Delta Y_{pbo} \leq \Delta Y_{drg} \end{cases}$$

To estimated the treatment assignment for the testing data, we tried two methods, longitudinal average slope methods and change score methods.

For the longitudinal average slope method, we used the ullback-Leibler divergence method to estimated $\hat{\alpha}$ and $\hat{\beta}_{drg}, \hat{\Gamma}_{drg}, \hat{\beta}_{pbo}, \hat{\Gamma}_{pbo}$. The the estimated fixed effects Z can be calculated as:

$$\begin{aligned} \hat{z}_{i,drg} &= S[\hat{\beta}_{drg} + \hat{\Gamma}_{drg} \hat{\alpha}' x_i] \\ \hat{z}_{i,pbo} &= S[\hat{\beta}_{pbo} + \hat{\Gamma}_{pbo} \hat{\alpha}' x_i] \end{aligned}$$

Given that, the estimated group assignment can be calculated as

$$\text{estimated group assignment} = \begin{cases} \text{Drug group} & \Delta \hat{z}_{i,pbo} > \Delta \hat{z}_{i,drg} \\ \text{Placebo group} & \Delta \hat{z}_{i,pbo} \leq \Delta \hat{z}_{i,drg} \end{cases}$$

The concordance proportion is then calculated as

$$\frac{\sum_{i=1}^N I(\text{estimated group assignment} = \text{true group assignment})}{N}$$

p.s. previous I used $\hat{z}_{i,drg} = S[\beta_{drg} + \Gamma_{drg} \alpha' x_i]$ and $\Delta Y = \hat{z}_{7,drg} - \hat{z}_{1,drg}$ as the true group assignment rule for the longitudinal method, instead of the true ΔY in the testing dataset.

For the change score method, the change in outcome Y can be fitted with a linear regression with covariates X , i.e.

$$\Delta \hat{Y} = \hat{\gamma}_1 x_1 + \dots + \hat{\gamma}_p x_p$$

where $\hat{\gamma}_i$ is estimated with the same model in training dataset. Then

$$\text{estimated group assignment} = \begin{cases} \text{Drug group} & \Delta \hat{Y}_{pbo}^{cs} > \Delta \hat{Y}_{drg}^{cs} \\ \text{Placebo group} & \Delta \hat{Y}_{pbo}^{cs} \leq \Delta \hat{Y}_{drg}^{cs} \end{cases}$$

The concordance proportion is then calculated as

$$\frac{\sum_{i=1}^N I(\text{estimated group assignment} = \text{true group assignment})}{N}$$

We would like to compare which method can achieve a higher concordance proportion.
